## OSMIRIDIUM IN TASMANIA

## Nature and Composition

Osmiridium (which is the name always used in Tasmania) or iridosmine is a native alloy composed essentially of the metals osmium and iridium in varying proportions. Two varieties have been made depending upon the relative proportions of the two metals, but as the composition of the mineral appears to range continuously from ore rich in iridium to those rich in osmium, the distinction is more or less an arbitrary one. These varieties are - nevyanskite (with over 40% iridium) and siserskite (less than 30% iridium).

Osmiridium has a colour ranging from tin-white (the most common) to light-grey, silver-white, bluishgrey, and yellowish-grey, with a metallic lustre ranging from dull to splendent and glistening.

It is slightly malleable to nearly brittle; has a hardness of 6 to 7; and a specific gravity of 18 to 21.

## Taamanian Osmiridium

The comiridium found in Tasmania is the nevyanskite variety. It is tin-white in colour and has a bright metallic lustre. It is obtained in flat flakes, and rounded grains of small size. The larger pieces and nuggets consist of aggregates of the above small pieces. The composition of Tasmanian comiridium is given in the following table:-

	N.W; Coast	Bald Hill	Mt Stewart	Adamsfield
Osmium	57.09	33.46	25.22	45.6
Iridium	33.80	58.13	46.12	41.3
Ruthenium	8.19	5.22	9.24	6.6
Platinum	0.37		0.13	1.2
Rhodium ]	Included with Iridium	3.04	4.37	0.3
Palladium	0,21		Trace	Trace
Iron			6.30	
G <b>ol</b> d			3.00	
Silica			3.71	

The first three analyses are those of individual samples, but that from Adamsfield represents the average of 19 accurate analyses. The Adamsfield samples have a very small range in composition and so the average given above represents very closely the general composition of the comiridium.

#### Nuggete

Tasmania has produced the largest nuggets of osmiridium found in the World. The details of the largest ones are given in the tables below:-

106

241

Ť

Ţ

Discoverer	Weigh	t (Troy	7)	Locality
	Çzs.	dwts.	grs.	
T. Prouse	4	6	6	Nineteen Mile Creek Heazlewood District
G. Nelson	2	8	8	Warner Ck. Heazlewood District
T. O'Malley	2	6	5	Ditto
C. Prouse	2	3	0	Nineteen Mile Creek Heazlewood District
Jas. Sweeney	ļ	19	<b>7</b> 🤱	Sweeney Creek, Wilson River District

North-Western Field

In addition to those mentioned above numerous other nuggets ranging up to 2 ozs. in weight have been found in these fields.

The largest nuggets from the Adamsfield district are as follows:-

Discoverer	Weight	(Troy)		Locali	ty
	0 <b>28</b> .	dwts.	grs	•

## Origin of the Osmiridium

Practically the whole of osmiridium has been obtained from alluvial and detrital deposits. When these deposits are traced to their source it is always found that this consists of an area in which bodies of serpentine occur. It can also be stated that these serpentine bodies are generally accompanied by veins and irregular bodies of coarsely crystalline enstatite. All serpentine bodies, however, do not contain osmiridium and it was established by A. McIntosh Reid, Government Geologist in 1921, that the osmiridium-bearing serpentines are those derived from peridotites containing orthorhombic pyroxenes such as enstatite and bronzite.

The same investigator also established the fact that the occurrence of osmiridium in these serpentines is restricted to pockety accumulations along definite structural plains in the rock.

#### Production

The total recorded production of osmiridium until the end of 1927 has been 20,671,598 ounces with a value of £481,831.

Year Quantity Value Ounces £ 1910 120 530 1911 271,88 1,888 778.77 1261.65 5,742 1912 1913 12,016 1914 1018.83 10,076 1915 247.048 1,581 222,150 1,899 1916 332.079 1606.743 1669.715 4,898 1917 1918 44,833 39,614 77,114 1919 1920 2009,196 42,935 35,512 1750.655 1921 1173.924 673.423 1922 1923 19,642 10,617 1924 364.805 103,570 61,908 3305.543 3172.50 1925 1926 632,687 7,456 1927

The annual production since 1910 has been as follows:-

# The Mining Fields

The principal mining fields were restricted to the north-western part of the State until the recent discovery of Adamsfield in the south central division.

The Bald Hill and Cavage River areas were the earliest known fields. These fields were worked for gold in the eighties of last century, when the osmiridion was of no commercial value and was regarded as a nuisance when obtained with the gold.

When uses were found for the mineral and a demand set in for it, the price gradually increased and the production rose accordingly.

The Mt. Stewart and Wilson River districts were discovered at later dates. From 1917 onwards work proceeded vigorously on all these fields. A maximum production of 2009 ounces was reached in 1920 and the production than decreased, due mainly to depletion of the richer deposits and also to a decrease in price. /

Adamsfield was discovered in 1925 and the resulting production caused the years 1925 and 1926 to be ones of record production. A collapse in the market price caused the decrease in 1926 and still greater one in 1927. At the same time the resources at Adamsfield are largely depleted and large productions will probably not be attained again.

## Mining Methois

The mining methods employed depend upon the local conditions of the deposits, the water supply, etc.

The most primitive method is panning or dishing. This is very slow and is only engaged in when water is not plentiful or "fossicking" is being carried out.

When the water supply is low and circumstances are favourable, "cradling" is employed in preference to dishing.

With a plentiful supply of water the alluvial ground is treated by methods such as "toxing" and "ground sluicing", which enable larger quantities to be treated.

Hyiraulic sluicing is not engaged in as the claims allowed (half acre per man) are too small to permit of water-supplies being provided by means of races etc. and nozzles employed.

## Uses of Tasmanian Osmiridium

The principal use of osmiridium is the supply of its component metals, iridium, osmium, etc. Of these iridium is the most important as it is alloyed with platinum in varying proportions for all purposes for which the latter is used. Russia is the largest producer of the platinum metals but it does not market osmiridium as such but as the component metals.

South Africa is at present the largest producer of native esmiridium having displaced Tasmania from that position during the last few years. There is a very important difference in the products of the two States, however, in that the South African esmiridium is very fine in grain, while the Tasmanian is very much coarser and ranges in size up to nuggets of several ounces in weight.

The South African metal is probably all treated and the refined metals produced. The Tasmanian product is however, particularly adapted for another very important industry, viz, the fountain pen one, because it furnishes grains of the desired size and physical characteristics suitable for putting tips on the gold nibs. Being eminently suitable for this particular purpose, it is much sought after and therefore commands a somewhat higher price.

The greater part of the Tasmanian osmiridium is undoubtedly used for this purpose, the remainder which is of unsuitable size and character, being treated in the refineries for the various metals.

### Price of the Metal

The average local price gradually rose from £4 per ounce in 1910 to £38 in 1919 and 1920. From 1920 the price fluctuated between £20 and £30 per ounce, the largest price -

ł

ť

being £32. 15. O per ounce at the end of 1925. During 1926 and 1927 the market declined to almost £10 per ounce but the present one is approximately £30 per ounce.
