Appendix 1: RFGT Scan Data	

## 1. Executive Summary

HardRock Coal Mining Pty Ltd (HRCM) engaged the services of Global Geological Group Operations Australia (GGG) Pty Ltd to undertake both an aerial and ground survey over their Exploration Licence (EL 17) at Fingal in north-east Tasmania and to provide follow-up work in the form of a single (1) vertical sounding confirmation scan (VSCS) in the south-eastern corner of EL 17.

The survey work and vertical soundings were conducted using GGG's revolutionary Resonance Frequency Geological Technology (RFGT) with the vertical sounding being located over the site of a previously drill hole (DR01).

There was no specific background information in terms of historical drill holes (i.e. petrology, mineralogy, coal quality etc.) or mining information provided in relation to EL 17 prior to the RFGT work being conducted although there was a reasonable understanding of the area from previous work which was conducted on the Exploration Licence (EL 16) to the east and north-east of EL 17.

The aerial scan work returned quite consistent results over the majority of the Exploration Licence (EL 17) and indicated that there was no material with a carbon content in excess of 50% indicating that any material present would best be described as a carbonaceous material and could represent very narrow, low-grade coal seams interspersed with very fine sediments or carbonaceous sediments where the carbon is attributable to fossiliferous plant matter.

The auto-profiling work was conducted using a motor vehicle to enable closer measuring points (100 metres) to be obtained and thereby a more detailed assessment. At each 100 metre interval the carbon content was measured to define the variation in the carbonaceous material encountered. The auto-profiling work determined that the maximum carbon content was around 32%.

A remote deep sounding or vertical sounding confirmation scan (VSCS) was conducted to a depth of 800 metres at the site of a previous bore hole, DR01. The VSCS scan did detect the presence of a carbonaceous seam approximately 2 metres thick at a depth of 543 to 545 metres. The average carbon content of the ply was 23% indicating that it was essentially a carbonaceous material with significant non-organic content (i.e. fine muds and silts).

The VSCS scan was conducted towards the southern-most boundary of the Exploration Licence (EL 17) but would still be considered to be well within the limits of the Tasmanian Basin. The lack of recognisable coal seams in EL 17 when compared to EL 16 to the east and north-east could be attributed to the presence of many steeply dipping faults in the region or even horst and graben structures which are known to have fragmented and dislocated the coal sequences.

The RFGT scan work essentially determined that EL 17 does not hold much promise for an economic coal deposit in terms of either coal quality or coal seam thickness. The material that was detected during the survey work could best be described as a carbonaceous material.

## 2. Introduction

Global Geological Group's (GGG) Resonance Frequency Geological Technology (RFGT) is an innovative, completely non-invasive and highly rapid means of exploring, assessing and mapping the subsurface environment in terms of its chemical, mineralogical and structural components.

This technology has been developed over the past 25 years by undertaking geophysical work involving original research and accepted applied geodynamics. The technology has been successfully applied to the exploration and assessment of hard rock and soft rock (oil, gas and coal) resources, groundwater systems and environmental issues, such as contaminant plumes.

In December 2011, HardRock Coal Mining Pty Ltd (HRCM) utilised both the broad and virtual borehole scanning capabilities of the RFGT technology over its eastern-most Exploration Licence (EL 16) located in the Fingal Valley in north-east Tasmania.

The primary driver at the time was to assess the capabilities of the RFGT technology and determining its potential to provide HRCM with accurate, "virtual borehole" data. This work proved successful and follow up work over HRCM's western Exploration Licence (EL 17) was initiated to determine if significant coal measures occurred within the lease area (Figure 1).

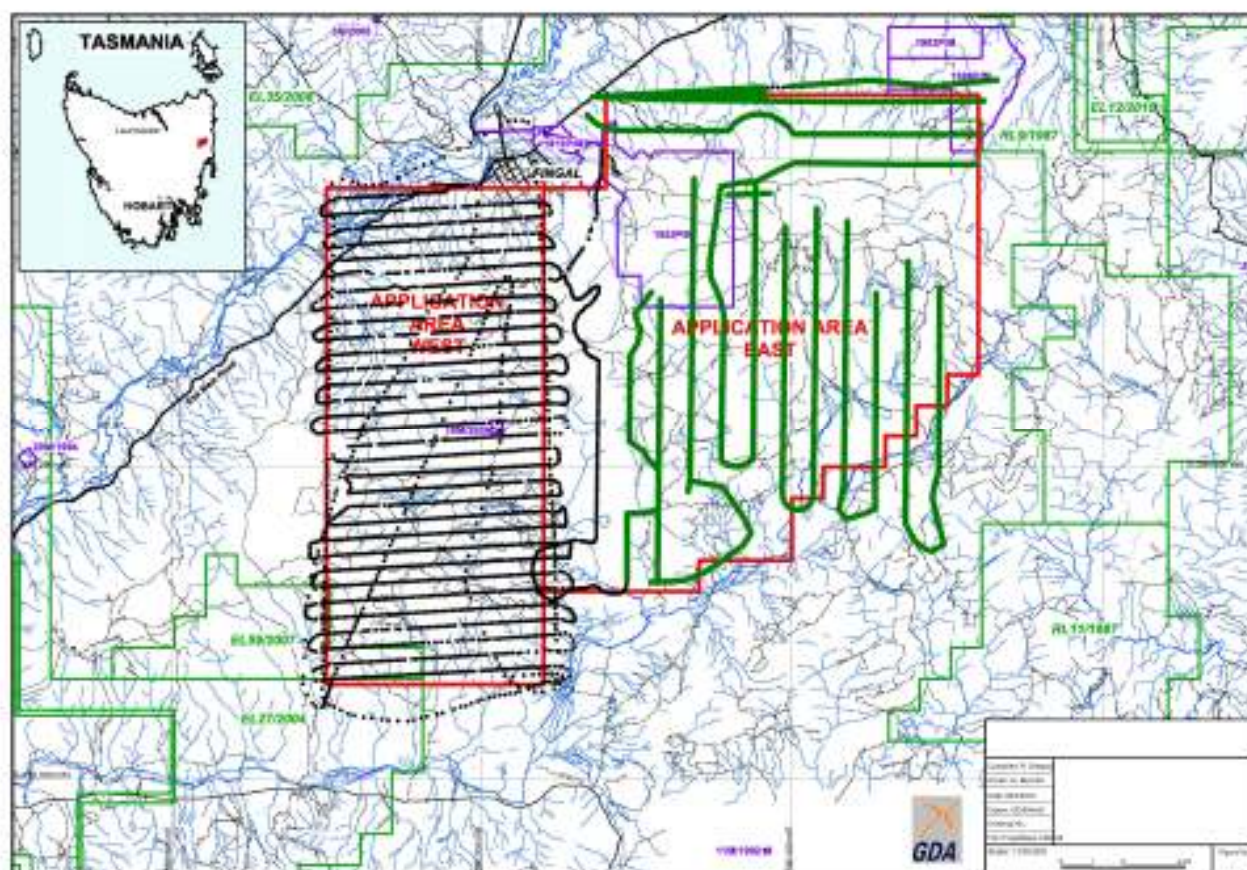

Figure 1: Location of Hard Rock Coal Mining's Exploration Licences - EL 17 (west) and EL 16 (east).

The RFGT survey work comprised broad aerial scanning followed by a 4WD survey (auto-profiling) to provide detailed fill-in work at 100 metre interval spacings (between readings) and finally one

vertical sounding confirmation scan (VSCS) near the southern boundary of the Exploration Licence (EL 17) to provide a very detailed assessment down to 800 metres depth.

### 3. Investigative Methodology

Both aerial and ground surveys were conducted over specified areas within the current Exploration Licence (EL 17) and these were then followed up with one (1) vertical sounding confirmation scan (VSCS) to provide more detailed information on the nature and make-up of the coal seams which are being targeted for extraction by Hardrock Coal Mining.

The vertical sounding confirmation scans work on the basis of monitoring, measuring and capturing the relative value of the natural electromagnetic field of the earth (NEMFE) that is generated by geologic objects and subjecting the full vector ( $I'$ ), horizontal ( $H_{xy}$ ), and vertical ( $H_z$ ) components of the magnetic strength to a specific data interpretation methodology.

The information is scientifically evaluated to develop detailed plans and cross sectional maps of the subsurface to a depth of 6,000 metres.

The GGG Resonance Frequency Geological Technology scans are conducted via light-radio frequency systems comprising:

- A control-measurement unit,
- An interface unit for electromagnetic oscillations,
- A GPS system,
- A portable CPU for data capture,
- Special antennae for sensing the entire spectrum of the NEMFE; and,
- Specialist software for data interpretation.

The output is presented in a graphical format that is dependent on the specifics of the investigation.

### 4. Local Coal Geology and Setting

Coal has been mined in various areas of Tasmania with major deposits of black coal being discovered in the Fingal Valley in 1863. The completion of the railway line to St Marys in 1886 enabled the establishment of larger scale coal mining in the Fingal Valley and this area has provided the majority of Tasmania's coal since that time (Hutton, 2009).

The coal seams of Tasmania are found within the Parmeener Supergroup which is essentially flat-lying and was deposited in a structural basin, called the Tasmania Basin which covers a large part of Central and eastern Tasmania. The rocks range in age from Late Carboniferous to Late Triassic. Structurally, the Tasmania Basin has several small tectonic folds with limbs dipping at 10° or less,

and drape folds over bedrock topography. The sequence has been intersected by many steeply dipping faults with displacements of less than 100 m. During the Late Cretaceous and Early Tertiary, horst and graben structures fragmented and dislocated the coal sequences (Hutton, 2009).

The Parmeener Supergroup was originally subdivided into four sequences (each composed of several formations) comprising, in stratigraphic order, the Lower Marine, Lower Freshwater, Upper Marine and Upper Freshwater Sequences. Bacon gave a revised stratigraphy and divided the Parmeener Supergroup into the Lower Parmeener Supergroup, comprising the Lower Marine and Upper Marine Sequences (marine and glacio-marine lutite, marl, minor limestone and a thick basal tillite), which is separated by the Lower Freshwater (all older than Permian) from the Upper Parmeener Supergroup, of fluvial origin, comprising the Upper Freshwater Sequence and an Above Upper Freshwater Sequence (Permo-Triassic age) – (Hutton, 2009).

The two sequences in the Upper Parmeener Supergroup are separated by a disconformity which represents a late Permian to middle Triassic hiatus between the Upper Freshwater Sequences and the younger Above Upper Freshwater Sequence.

The Parmeener Supergroups were extensively intruded by dolerite derived from tholeiitic magma during the mid-Jurassic. The dolerite mostly occurs as discordant sills, up to 550 metres thick, which form a nearly continuous body. Dykes have been recorded. The dolerite is thought to represent more than 8000 km<sup>2</sup> of magma (Hutton, 2009).

The discontinuous Late Triassic coal sequences cover much of eastern and southern Tasmania (including the study area). Triassic coals are found in fining upwards sequences comprising sandstone representing channel deposits and siltstone and coal representing overbank deposits which were deposited on a flood plain with many streams of moderate to low sinuosity and frequently changing direction. Overall the coal measures have a higher proportion of sandstone, indicating classical high sinuosity meandering streams. The economic seams are within the Triassic deposits (Hutton, 2009).

Although small scale mining has occurred at many localities where the Triassic coal measures are found, the three main coalfields are the Fingal Coalfield (centred on Fingal Tier), Mt Nicholas Coalfield (in the Nicholas ranges north-east of Fingal Tier) and Dalmayne Coalfield (east of the Fingal Coalfield) which are located in the northeast corner of the state. These coalfields contain the bulk of the Tasmanian coal resources. The Lower Parmeener Supergroup is up to 120 metres thick in these coalfields and is controlled by erosion. The Upper Parmeener Supergroup which hosts the coal seams is 350 metres thick (Hutton, 2009).

Eight coal seams are found in the Fingal Coalfield, designated seams A to H although the upper two seams are very poor quality verging on being carbonaceous shale. The most economic seams are the Duncan (F) seam and the East Fingal (H) Seam which is stratigraphically 30 metres below the Duncan Seam. The Blue Seam is mined at Blackwood Colliery on Mt Nicholas and the Merrywood Seam has been mined in an open pit operation southwest of Fingal (Hutton, 2009).

Late Triassic coal is a very dull coal that formed in a dry forest moor environment, with ash 25 to 30 per cent, specific energy 20 to 24 MJ/kg (air dried); vitrinite reflectance is 0.5 to 0.6 per cent although coal affected by the dolerite sills has a much higher rank with vitrinite reflectance up to 3

per cent. Sulphur is much lower than for the Permian coals, approximately 0.5 per cent. Typical maceral analyses give 60 to 70 per cent inertinite, 10 per cent vitrinite and 5 to 10 per cent liptinite (Hutton, 2009).

The Duncan Seam comprises 2 to 3 metres of dull coal with minor claystone and mudstone interbeds. Raw ash is approximately 30 per cent and the specific energy is 22 to 24 MJ/kg. Vitrinite content in the Duncan Seam is higher than the average, up to 30 per cent. The East Fingal Seam is generally split, with 1 to 2 metres of coal with intraseam clastic rocks up to 10 metres thick. Coal quality is similar to that of the Duncan Seam (Hutton, 2009).

## 5. Survey Results

The aerial scan work conducted over Exploration Licence 17 (EL 17) returned quite consistent values, indicating that significant coal seams were not present in the lease area (Figure 2).

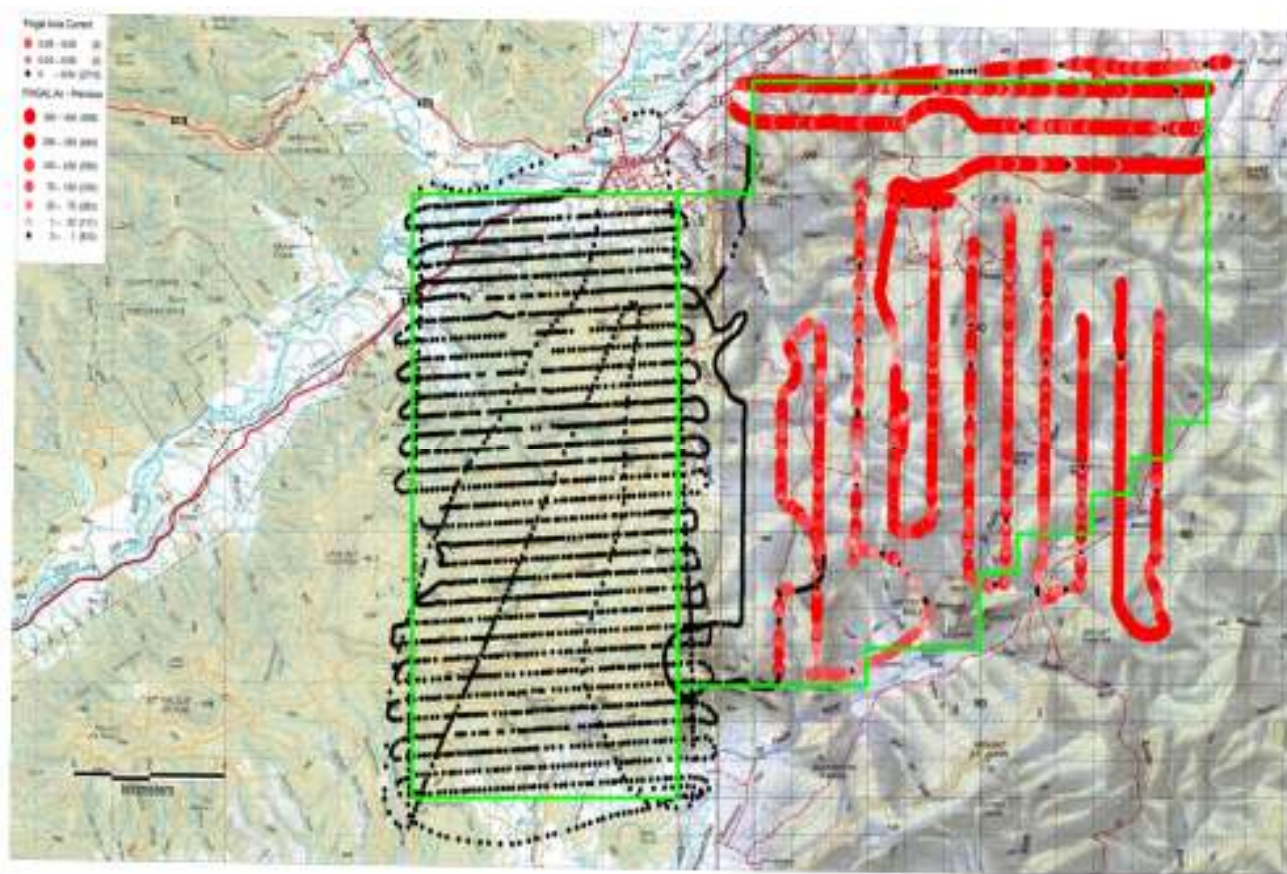

Figure 2: Location of EL 17 (western area) showing aerial survey work with EL 16 to the east and north-east showing substantial coal (red) intersections.

The aerial scan work for EL 17 was in stark contrast to that in EL 16 which showed significant coal intersections. Given that EL is not on the verge of the Tasmania Basin it is possible that the lack of coal in EL 17 is due to steeply dipping faults dislocating the coal beds elsewhere or the presence of horst and graben structures which are known to have fragmented and dislocated the coal sequences.

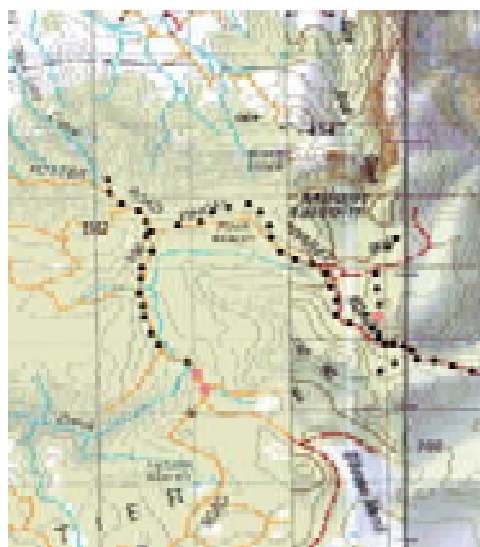

The aerial scanning work was followed up with some auto-profiling (via 4WD vehicle) which was used to test in more detail some of the area within the Exploration Licence (EL 17) on the eastern border (Figure 3).

Figure 3: Auto-profiling trace across the eastern boundary of EL 17 and into adjoining EL 16. DR01 is shown as a small red star in the bottom south-eastern corner of the western half of the diagram (EL 17).

The auto-profiling essentially targets those areas that the aerial scanning work identifies as having the potential for mineralisation and seeks to provide a higher level of detail.

Figure 4 is an enlarged portion of Figure 3 and shows the trace from auto-profiling work conducted near the boundary between EL 17 and EL 16 to the east. The RFGT unit was calibrated in this program of work to specifically respond to carbon content and as such had a high level of sensitivity to carbon levels. The small black dots are indicative of either no mineralisation or, at best, very low levels of mineralisation, in this case, the presence of coal.

The larger pink dots are indicative that the auto-profiling was able to detect some carbonaceous material at depth but this was considered to be a mix of sediments and either low grade coal or fossiliferous plant material. Heavy red dots are indicative of significant mineralisation but these did not occur in EL 17.

The auto-profiling indicated that these carbonaceous layers comprised a carbon content of less than 32% carbon and as such could not be deemed worthy of further investigation

Figure 4: Enlargement of portion of EL 17 where auto-profiling was conducted.

Following the auto-profiling a vertical sounding confirmation scan was conducted in the far south-eastern corner of the Exploration Licence 17 (EL 17) and this level of scan provides the highest degree of definition for detailed assessment of a mineralised system

The vertical sounding confirmation scan results for DR01 comprises a graph (trace) which depicts the thickness and location of the coal horizons, the number of coal seam plies present and an indication of the coal seam quality by way of a percentage of coal versus non-coal materials. This percentage essentially represents interdigitating coal and lithic sediments (sandstone, siltstone and mudstone) as opposed to coal seam plies which indicate intercalated sequences (non-coal layers between coal seams).

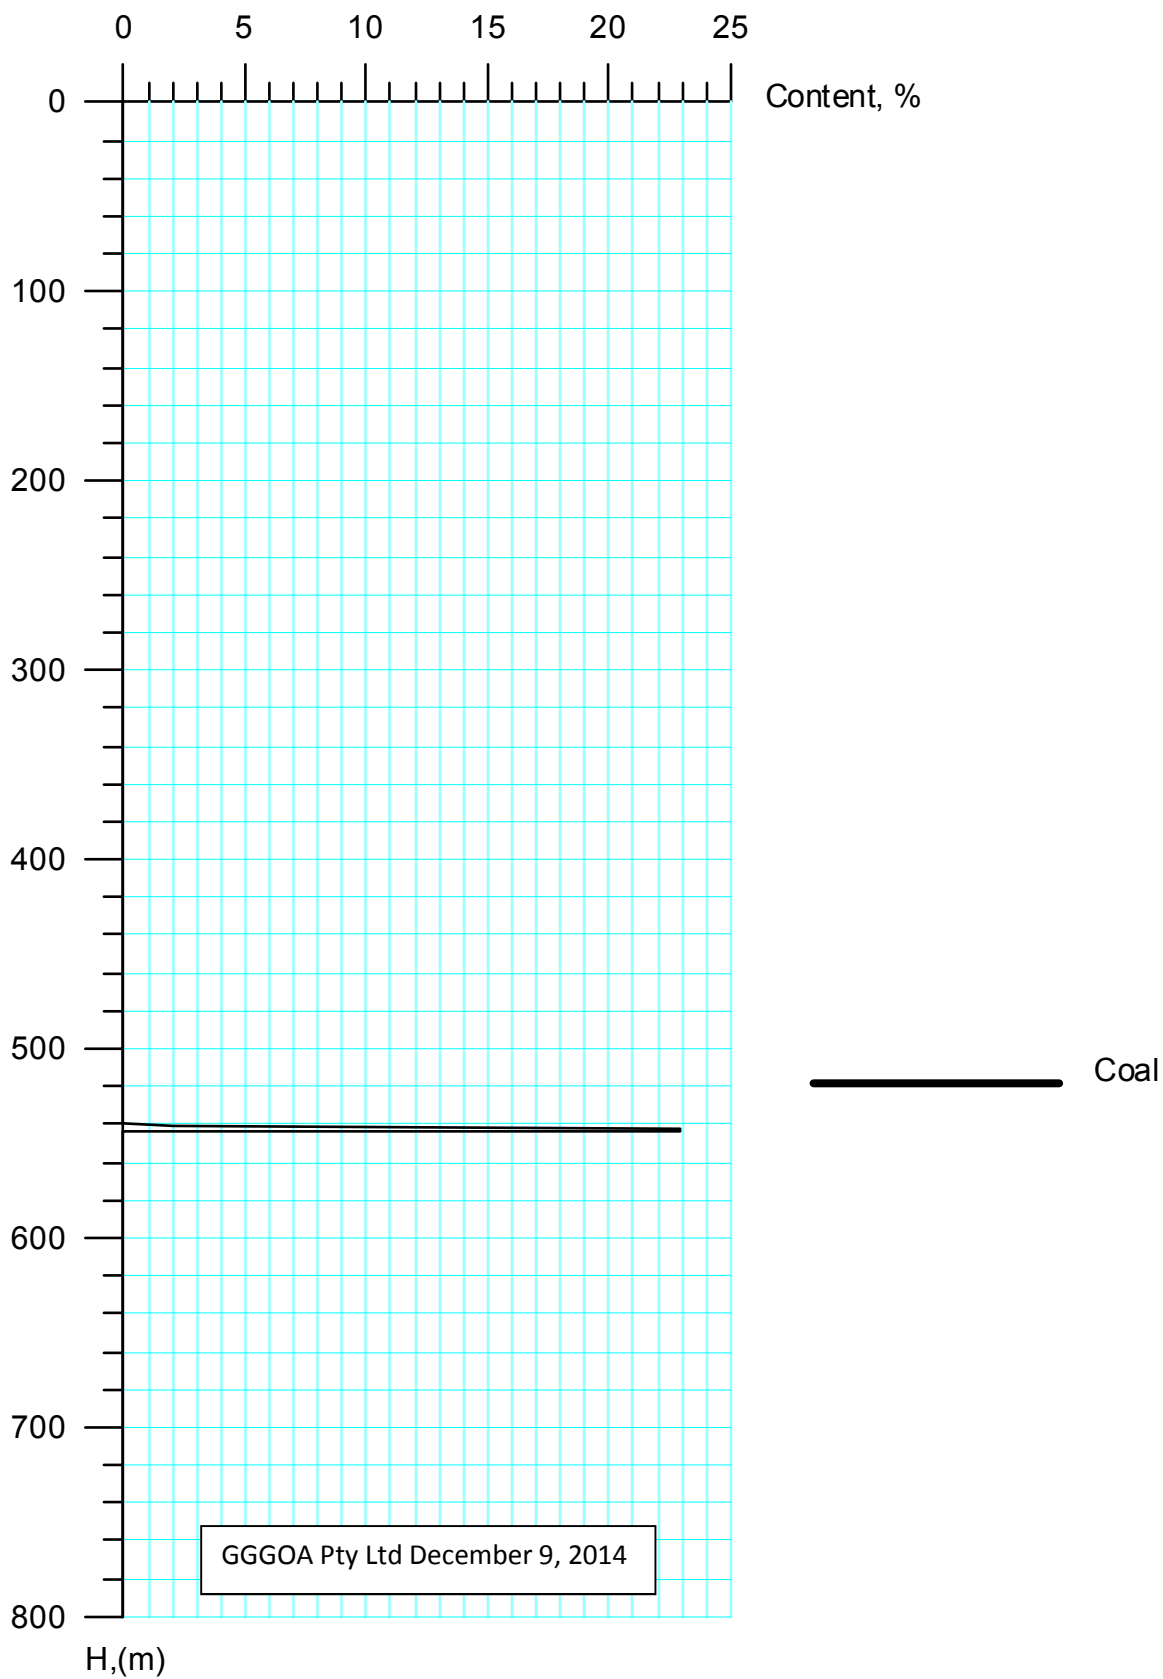

The graphs / traces for the vertical sounding for DR01 are attached below:

The single vertical sounding was located towards the south-eastern corner of the Exploration Licence (EL 17) near the site of an historic drill hole (DR01). The vertical sounding was conducted to a depth of 800 metres below ground level (mBGL). The vertical sounding detected a single low-grade coal seam (carbonaceous material) between 543 and 545 metres BGL with a carbon content of approximately 23 %.

The graphs / traces for the vertical sounding are attached below with the second graph being at a larger scale in order to enable the carbonaceous unit to be assessed in more detail.

## 6. Discussion

According to the data that has emerged from the aerial, ground and vertical sounding scans, using the RFGT technology, there is a strong consensus that Exploration Licence 17 (EL 17) does not contain a coal resource of any significance but rather the occurrence of patchy carbonaceous material with a low to moderate carbon content and very thin seam / ply thickness.

The results from the RFGT scan work from a broad to a detailed scale indicate that there is little likelihood of the occurrence of coal of sufficient grade and quantity to warrant further work on Exploration Licence 17 (EL 17).

The contrast with the adjoining Exploration Licence 16 (EL 16) to the east and north-east could possibly be due to the occurrence of horst and graben structures which have dislocated the coal seams that are known to exist in this part of the Tasmania Basin such that they have either be translated to greater depth or uplifted and exposed to weathering and erosion.

This particular hypothesis would need to be tested via stratigraphic drilling or similar work which is well outside of the scope of this investigation.

## 7. Closing Statements

The information in this report has been compiled by Andrew Graham who is a 20 year member of the Australasian Institute of Mining and Metallurgy. Mr. Graham has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration to qualify as Competent Persons as defined in the JORC Code 2004. Mr. Graham consents to the release of the information compiled in this report in the form and context in which it appears.

Mr. Graham also has sufficient experience in the Resonance Frequency Geo-Technology (RFGT) to enable him to make specific determinations in relation to the output data provided.

Mr. Graham does not accept responsibility for any errors or omissions in the supplied information and does not accept any consequential liability arising from commercial decisions or actions resulting from them.

A handwritten signature in black ink, appearing to read 'A.M. Graham', with a stylized, flowing script.
