III Summary of Diamond Drilling in the Dundas Area of West Tasmania, September 1972 - February, 1973.

IV Geochemical Laboratory Reports

V Diamond Drilling Records

INTRODUCTION

The purpose of this report is to present a final appraisal of the results obtained from the drilling and underground sampling programs undertaken by Geophoto Resources Consultants on behalf of Texins Development Pty. Ltd. in the Kosminsky-South Comet prospect.

Conclusions are also offered on the economic value of the mineralisation, as exposed in the Great South Comet mine, and as defined by the borehole intersections obtained in the area.

It must be noted here that by "Kosminsky-South Comet zone of mineralisation" we mean a section of a major northwest trending fracture zone comprised between two subparallel lines of gossanous outcrops (as outlined on Drg. B160) and within which several mineralised trends have been recognised.

Other mineralised trends, the surface expression of which lies east of line of gossans "A" (refer to Drg. B160), are dealt with for convenience in this report but do not, strictly speaking, belong to the "Kosminsky-South Comet zone".

In Geophoto Minerals Report 1974/4, the "zone" has been subdivided into four sections (refer to Drg. 1.359 : Kosminsky, South Comet, Climie, Mariposa. The latter two, which have not been tested by diamond drilling nor have undergone any mining development during the early times of the Dundas field, will not be considered in this report.

For more information regarding the historical background of the exploration of the area and the rationale for the drilling activity from 1968 to 1973, the reader is referred to Geophoto Minerals Reports 1969/10, 1970/38a and 38b, 1971/49, 1972/9, 1972/10, 1972/11 and the latest Minerals Report, 1974/4 which complements this report.

TITLE

Throughout most of the time the exploration activity was carried out, the prospect area was held by Texins Development Pty. Ltd. under E.L.7/68 (refer to Geophoto Minerals Report 1974/4), with the exception of two Mineral Leases: 1M/69 and 2M/69 totalling 68 acres, held by a local prospector, J.A. Smyth.

After arranging an option agreement in 1969, Texins Development Pty. Ltd. decided in December, 1972 to purchase the two mineral leases.

On 20th February, 1974, three days before the date of expiry of E.L.7/68, Texins Development Pty. Ltd. lodged applications with the Department of Mines for two mineral leases, of 80 ha and 61 ha respectively, contiguous to the two already held in the prospect area. (refer to

At the date of this report, the endorsement of the Department of Mines is still pending.

LOCATION AND ACCESS

The prospect area is located on the West Coast of Tasmania, about seven miles east of Zeehan.

Access is provided by the Queenstown-Burnie sealed road and by a track (refer to Geophoto Minerals Report 1974/4, Drg. B.374) which departs the main road at about 3,000 feet northeast of the Zeehan junction, and is negotiable by two wheel drive vehicle only as far as the old Maestri Mill site. Beyond this point the track is negotiable all year only by 4-wheel-drive vehicles as far as the Great South Comet mine Adit No. 1. It becomes winding, steeply graded and easily washed out from the lower slopes of the South Comet hill to the end, about 200 feet south of Adelaide Mine Creek.

MINING HISTORY AND PRODUCTION RECORDS

Very little is known about the early history of mining in the prospect area, and only a few old production records and assay returns are still available.

Prospecting had started by 1890 in the Kosminsky Hill and some mining development started in 1891 in what was to be called the "Kosminsky mine" at about 1,000 feet downstream from the location of the later Adit No. 1 of the Great South Comet mine.

Two more adits were driven in the following years but production was apparently very limited, and only small, high grade pods were worked, as shown by the following assay return for an unknown amount of ore material extracted from Adit No. 1 of the mine (refer to Reid, 1925).

Pb = 52.2%
Zn = 13.18%
Ag = 24 oz

According to Blisset (1960), the 1901 figure of 20 tons of ore from which 10 tons of Pb and 480 oz of Ag were recovered, should represent the bulk of the production of this mine.

The area of the Great South Comet mine was first leased in 1911 by the Comet Tribute Prospecting Syndicate N.L. and was held until 1950 by various syndicates and small mining companies. However, most of the development (Adit 1, Adit 3 and Adit 4) was undertaken prior to 1925. After 1950 only minor stoping was carried out in Adit No. 1.

Production records are rather incomplete:

1911?-1925: 1,000 tons of "ore" of unknown grade were extracted (Reid, 1926).

1925-1935: In 1927 a flotation plant was constructed by Comet Tribute Prospecting Syndicate. A record shows that in that year, the "ore" material extracted from Adit No. 3 yielded

Pb	121 tons
Zn	378 tons
Ag	10,806 oz

1935-1937: The Griffith Tribute party produced in two years about 19 tons of ore which yielded

Pb	11 tons
Ag	868 oz

1937-1948?: Texco Montana Silver-lead Dev. Co. produced 350 tons of unknown grade.

1948-1950: Lead and Nickel Mining Co. produced from about 27 tons of concentrate

Pb	22 tons
Ag	1664 oz

I Gregory (1959) estimates that the maximum production of the mine to date should be about 3,400 tons of material of unknown grade.

DEVELOPMENT

The Kosminsky-South Comet mineralisation has been worked in both sections of the fracture zone although the bulk of the production comes from the South Comet section.

1. Kosminsky Hill Workings

At least four short adits, one shaft and several trenches, now mostly overgrown by the vegetation, were put into the Kosminsky hill in the early times of the field.

A short adit is located at 16S + 15.5W of the Comet-Kosminsky grid. The dump material shows abundant siderite with stringlets of galena and sphalerite.

The Kosminsky shaft, located at 20S + 14W + 80ft north of the Comet-Kosminsky grid is collapsed, but is thought to have been 50 feet deep. Dump material shows galena and sphalerite with minor chalcopyrite in a siderite-pyrite gangue.

Minor economic sulphides mineralisation is also observable in the dump material of three short adits located between lines 22S and 24S of the same grid.

2. "Kosminsky Mine" Workings

These workings are between 800 and 1,050 feet west of Adit No. 1 of the Great South Comet Mine, and consist of a shaft and three adits shorter than 300 feet. The dump material shows coarse sphalerite and galena in a siderite gangue.

The erratic pods known to have been worked in the mine should probably be correlated with Geophoto's trend W.

3. Great South Comet Mine

Three lodes (refer to Drg. B162 - Trend A) were worked in the South Comet section by means of four adits driven from the northern slopes of the South Comet hill, and by three more adits driven from the Adelaide mine creek in a northerly direction. However, Adit No. 1 and Adit No. 3 represent 85% of the development of the mine, and the bulk of the production came from Stope No. 7 and No. 8 of Adit No. 3.

It is to be noted that the mining method followed in the early days of the field was that of only stoping galena-rich pods, ceasing operations whenever sphalerite-rich pods were found, either, as Taylor (1950) advises, because there was no market for zinc ore or, as McKenna (1958) suggests, because the old treatment plant at the mine was never satisfactorily equipped to separate galena from sphalerite in the concentrate.

Adit No. 1 (1,124' A.S.L.)

Adit No. 1 was driven on to Lode A3. At 850 feet from the portal a rise, now inaccessible, connected with a winze sunk from Adit No. 3 (1,337' A.S.L.).

Ten feet past the foot of the rise the roof has fallen and it is not known how far the drive extends past this point.

Three crosscuts were driven from the main drive. No. 1 West Crosscut starts at 520 feet from the portal and penetrates the country rock for 172 feet. No. 2 West Crosscut and No. 1 East Crosscut were driven at 805 feet from the portal. At 12 feet from the entrance of No. 1 West Crosscut a drive was put in a southerly direction for 30 feet, with the purpose, apparently, of bypassing the obstruction in the main adit (Taylor, 1950). Some minor underhand stoping was, however, carried out on Split 'Beta' (McKenna, 1959). No.1 East Crosscut was driven for 44 feet and exposes Lode A2 and Lode A1.

Minor stoping operations were carried out above the level of the adit over a maximum vertical distance of 40 feet (refer Drg.

Adit No. 2 (1,246' A.S.L.)

Adit No. 2 is 40 feet long and exposes very minor mineralisation. No stoping was carried out.

Adit No. 3 (1,337' A.S.L.)

Lode A1 was intersected at 110 feet from the portal and followed for 240 feet. A section of the lode, 220 feet long, was stoped over a maximum vertical distance of 50 feet above the level of the adit (Stope No. 7). At 320 feet from the portal a crosscut in a south-westerly direction exposed Lode A2 and Lode A3. Lode A3 was followed, and probably stoped, over a length of 280 feet and a vertical distance of less than 40 feet (Stope No. 8). Lodes A2 and A3 were intersected also in No. 3 and No. 4 West Crosscuts but minor drifting along the strike of the lodes was undertaken. (Refer to Drg. No. B.162).

Adit No. 4 (1,474' A.S.L.)

Adit No. 4 was driven for 140 feet on to Lode A3 but no stoping was carried out.

Adits No. 5, No. 6 and No. 7

These adits are short and partly inaccessible at the present time. They were driven from the Adelaide mine creek in a northerly direction. No stoping was carried out.

EXAMINATION OF THE PROSPECT AREA BY GOVERNMENT AGEACIES AND COMPANIES OTHER THAN TEXINS DEVELOPMENT PTY. LTD.

1950 - Department of Mines, Tasmania

B.L. Taylor undertook the evaluation of the Great South Comet mine operated at that time by Lead and Nickel Co. N.L. All the adits were surveyed by theodolite and mapped.

26 samples were collected and assayed for Pb, Zn, Sb and Ag.

Taylor estimated "proved reserves" of 60,000 tons of ore averaging 8% Pb, 7.4% Zn, 8 oz/ton Ag, and about 300,000 tons of "probable and possible ore".

1958-1959 - Rio Tinto Australian Exploration Pty. Ltd.

D. McKenna and I. Gregory carried out a surface and underground investigation in the area of the Comet and South Comet Mines. I. Gregory collected 22 samples from Adit No. 1 and Adit No. 3 of the South Comet mine and had them analysed for Pb, Zn, Cu, Ag, Au and Fe. His conclusions differed from Taylor's and he pointed out that the only lens of the South Comet mine with economic sulphides mineralisation of "ore grade" was Lens L13N (Geophoto's Lens No. 5) for which he estimated a maximum tonnage of 7,000 tons averaging 8.6% Pb, 19.1% Zn, 0.09% Cu and 5.7 oz/ton Ag.

TEXINS DEVELOPMENT PTY. LTD. ACTIVITY IN THE PROSPECT AREA: EXPLORATION TARGET AND METHODS OF EXPLORATION

1. Exploration Target

In January, 1973 Texins Development Pty. Ltd. defined its exploration target in the E.L.7/68 area as a lead-zinc deposit with a minimum tonnage of 2,000,000 tons of ore material at minimum average grade of 10% Zn or 13% of combined zinc and lead.

2. Methods of Exploration (Summary)

The prospect area was gridded and mapped in detail at scale of 1 inch = 100 feet (Geophoto Minerals Report 1969/30, Drg. 1-203). V.L.F.-E.M., Self Potential and Magnetic surveys were carried out over the grid lines. Only limited rock and soil sampling surveys were undertaken owing to the lack of outcrops and to contamination from old workings (refer to Geophoto Minerals Report 1974/4).

Adit No. 1 of the South Comet mine was sampled in detail through close spaced channels cut, wherever possible every five feet, across the back of the drive. Altogether 342 samples were collected and assayed for Pb and Zn as a routine, and for Ag and Cd where the Pb and Zn contents were above 1%.

Combined drift assays defining five major lenses along Lode No. 3 are plotted on Drawing No. B.162.

47 boreholes, for a cumulative footage of 29,918 feet, were drilled in the prospect area. The results are discussed in detail in Geophoto Minerals Reports 1972/9 and 1974/7.

GEOLOGY (SUMMARY)

1. Stratigraphy (refer to Drg. 1.359, 1974/4)

The oldest rocks in the prospect area are the graphitic black slate and the micaceous grey quartzite of the Oonah formation (Upper Proterozoic). They are exposed along the South Comet track, 400 feet northeast of Kosminsky Hill 10 and K.H. 11 diamond drill sites, and near South Comet and S.C. 15 sites. In the first case they are at fault contact with the pink and mauve argillites of the Crimson Creek formation (Lower Cambrian) which are next in the stratigraphic sequence.

In the second case the contact is conformable. South of the South Comet fault, the greywacke-shale-conglomerate sequence of the Dundas Group (Cambrian) has been folded into a broad synclinorium, the axis of which strikes northeast. The basal member of the formation, the Red Lead conglomerate, is exposed along the road at about 100 feet west of the Adit No. 1 portal. The following members are exposed along the road which climbs up the South Comet hill.

On the 1 inch = 100 feet geologic maps of the South Comet and East South Comet grids, the stratigraphic boundaries of each member of the succession have been tentatively outlined. However, owing to the lithologic similarity of different stratigraphic units and to the lack of easily recognisable key beds above the Razorback formation, any subdivision which is not supported by palaentological evidence is open to question.

2. Structure

The Kosminsky-South Comet fracture zone is the most important structural feature of the area and can be described as a system of closely spaced tensional faults and joints with a general north-west trend and south-west dip ranging from 50^{o} to 80^{o}. It originated in the late stages of the Tabberabberan orogenesis and provided the channelways along which the mineralising solutions were emplaced.

At its northernmost extremity the fracture zone ends against a major west - north-north-east trending fault which marks the contact between the Oonah and Crimson Creek formations. (Refer Drg. No. B.160).

To the south it extends past the Adelaide mine creek and probably ends against the Montezuma fault (refer to Geophoto Minerals Report 1974/4).

The South Comet fault is a left wrench which has also been recognised and described by earlier authors (Taylor (1950) and McKenna (1958)). It offsets the fracture zone into the Kosminsky and South Comet sections, and this indicates that although the fault could have originated during the Tabberabberan orogenesis, minor horizontal movements took place also in post mineralisation time.

MINERALISATION

Fissure veins formed by stringlets, blebs and occasionally pods of galena and sphalerite in a gangue of siderite with minor other carbonates and little pyrite, are located within the fracture zone.

The distribution of the pods of economic sulphides is very erratic. They are lenslike, narrow, generally lowgrade and alternating with long, almost barren sections, as shown by the underground sampling of Adit No. 1 (refer to Drg. B.162 and B.163).

Galena and sphalerite never occur finely intermixed, and are always megascopically distinguishable. Often, along the same vein, pods of galena with very minor sphalerite, alternate with pods of sphalerite with very minor galena.

The iron-rich variety of sphalerite (marmatite) is very common, in particular in the South Comet section.

Chalcopyrite and jamesonite have been very seldom recognised.

In Adit No. 1, footwall and hanging wall of Lode No. 3 (A3) are usually well defined, although minor blebs and stringlets of economic sulphides can be often observed on the wall rocks.

No evidence of significant country rock replacement has been recognised.

Drawing B160 shows the main mineralised trends as defined from the borehole intersections and the underground reconnaissance of Adit No. 1 and No. 3 of the Great South Comet mine. In sequence from west to east they are:

1. Trend W

Trend W was intersected by boreholes both in the Kosminsky and in the South Comet section of the fracture zone where it exhibits better continuity and better grade. The section, between S.C.1 and S.C.17, yielded a well defined, although weak, E.M. anomalous indication recorded in the V.L.F. reconnaissance survey carried out over the South Comet grid.

The trend has not been tested by diamond drilling south of borehole S.C.19. (Refer to Drg. No. B.160).

2. Trend A (Refer to Drg. Nos. B.160, B.162, B.163).

This trend can be correlated on the surface with a discontinuous line of major gossan outcrops recognised both in the Kosminsky and in the South Comet sections. In the South Comet mine Trend A is formed by three lodes, called, from east to west, Lode A1, Lode A2 and Lode A3. The width of the "lode zone" is variable and can be accurately measured only in three places in the Great South Comet mine:

No. 1 East Crosscut, width = 42 feet
No. 3 West Crosscut, width = 38 feet
No. 4 West Crosscut, width = 25 feet

The interval between lodes in the Great South Comet mine is:

No. 1 East Crosscut,	A1, A2 = 12 feet) A2, A3 = 14 feet)	Elevation 1,124ft
No. 3 West Crosscut,	A1, A2 = 20 feet) A2, A3 = 5 feet)	Elevation 1,337 ft
No. 4 West Crosscut,	A1, A2 = 10 feet) A2, A3 = 5 feet)	

The three lodes can also be distinguished in the vertical sections of several bore holes drilled in the area. In some instances, however, the veins show a tendency to split and merge and, owing to the close spacing between them, it is often difficult to tell in a bore hole section the individual lodes from their splits. The three lodes seem to merge south of S.C.4. The following is a review of what can be learned on the size, composition and grade of the lodes from underground reconnaissance and diamond drilling:

Lode A1

In the mine Lode A1 was followed by Adit No. 3 and, over a short distance, by a drift put in from No. 1 East Crosscut of Adit No. 1. Taylor (1950) estimates an average width of 3 feet for this lode. Bore hole intersections at different levels show, from 655 feet to 978 feet, an average width close to 4.5 feet. The 14.1 feet wide mineralised intersection of S.C.11A at 1,185 feet is interpreted as formed by the merging of Lode A1 with Lode A2. Owing to the present condition of Adit No. 3, Lode A1 was sampled by Geophoto only along the short drift parallel to Adit No. 1. Over a strike length of 47 feet and a width of 3 feet, the lode averaged 1.67% Pb, 7.79% Zn and 0.9 oz Ag.

Lode A2

Lode A2 was exposed in the mine in Crosscuts No. 3 and No. 4 West and No. 1 East. This exposure was sampled by Geophoto and assayed over a width of 3 feet 0.6%Pb, 2.2% Zn and 0.4 oz Ag. Only two bore hole intersections show better grand and width, S.C.14, 803' A.S.L. and S.C.2A, 966' A.S.L.

Lode A3

Lode A3 was exposed in the main drive of Adit No. 1 and in the final part of Adit No. 3.

The channel sampling of Adit No. 1 has shown that the lode is formed by five galena-sphalerite lenses separated by long, lower grade or barren, sections. The length of the lenses ranges from a minimum of 35 feet to a maximum of 150 feet or probably more if we consider that most of the stope areas were not sampled and that Lens No. 5 is open at its southern extremity.

Lens No. 5 (refer to Drg. B.164) is the one which exhibits better continuity of "ore grade" averaging over a length of 70 feet and a width of 7.5 feet, 3.47% Pb, 11.47% Zn and 2.41 oz Ag. An important feature is the splitting up of this lens toward the end of the main drive into two branches, 'Alpha' and 'Beta' from east to west. Split 'Alpha' was followed and partly stoped in the main drive but the roof of the adit has collapsed 10 feet past the nearby rise to Adit No. 3, and no sampling was carried out by Geophoto. Split 'Beta' was crosscut near the junction of the two splits, and minor drifting in a southerly direction was undertaken. This split was regularly channel sampled and the assays obtained from the sampling of the face (channel 165) show that ore grade persists at the end of the drift. The splitting up of Lens No. 5 is also shown by boreholes S.C.11 and S.C.11A and probably S.C.10. Boreholes S.C.11 and S.C.11A show that at about 100 feet below the level of the adit, branch 'Alpha' (1,027' A.S.L.) still exhibits pay width and grade while branch 'Beta' (1,058' A.S.L.) is narrow and low grade. At about 80 feet above the level of the adit the width of branch 'Alpha' (1,201' A.S.L.) is still considerable but the grade has deteriorated, and branch 'Beta' (1,210' A.S.L.) is low grade although both metals content and width are better than in 1,058' A.S.L. intersection. The width of the mass of country rock between branch 'Alpha' and branch 'Beta' appears to range from 5 feet to 10 feet in bore holes S.C.11 and S.C. 11A.

3. Trends E2, E1, K.H.E.2, K.H.E.1

These are east of trend A and do not, strictly speaking, belong to the Kosminsky-South Comet zone of mineralisation. They have been mostly intersected by boreholes drilled to test the Kosminsky section of the "zone" and occasionally exhibit pay width and grade.

Trend E2

Bore hole K.H.3: 6.7 ft - 13.84% Pb, 2.37% Zn, 3.02 oz Ag

Trend E1

Bore hole K.H.1: 7 feet - 14.5% Pb, 1.72% Zn, 13.07 oz Ag

They do not, however, seem to have a better continuity along the strike than trend A or trend W.

ORE TONNAGE ESTIMATE

Owing to the lens-like nature of the veins, shown in Adit No. 1 of the Great South Comet mine and confirmed by the results of the drilling, as well as to the erratic distribution of the "ore" values, any projection of shoots or pods of mineralisation becomes rather conjectural. Estimated tonnages of ore in semideveloped or undeveloped lenses can therefore be offered only as a reasonable possibility.

It is also to be pointed out that, in our calculations, we will consider only those sections of the veins which exhibit an economic sulphides content in line with Texins Development exploration target as reviewed in January, 1973, namely a minimum grade of 10% Zn or 13% Pb + Zn.

In estimating the dimensions of the lenses we will take into account that in the Great South Comet mine: (Dwg. B.163)

1. The maximum horizontal distance over which a lens has been stoped ranges from 220 feet (Stope No. 7) to 280 feet (?) (Stope No. 8).

2. The average vertical distance of overhand stoping is 40 feet, with a maximum of 50 feet (Stope No. 7).

3. Very minor underhand stoping was carried out in Adit No. 1 but it is not known to what depth.

The following are the tonnage estimates for each lens exhibiting pay grade and pay width values.

1. Trend W

We will consider that section of the mineralization comprised between the intersections of boreholes S.C.1 and S.C.14. The two pay intersections are in a vertical range of 38 feet which is consistent with the average vertical dimension of the lenses stoped in the Great South Comet mine.

The influence of each intersection can be extended laterally half its distance from the nearest holes, both in a northerly and in a southerly direction, for a total strike length of 260 feet.

In our calculations, the west split of the vein structure will not be considered because it averages below the exploration target minimum grade.

611022

TREND W: ORE TONNAGE ESTIMATE

D.D.H.	Factor	Width	% Pb	% Zn	Ag (oz)	WxF	WxFxPb %	WxFxZn %	WxFxAg
S.C.1 (1,044')	2	4.5ft	4.58	13.5	1.52	9	41.22	121.5	13.68
S.C.2 (1,082')	2	5.2ft	13.4	1.4	0.13	10.4	139.36	14.56	1.35
	4					19.4	180.58	136.06	15.03

Combined assay average over a strike length of 260 feet

Width $= \sum \frac{WxF}{F} \doteq \frac{19.4}{4} = 4.85$ feet

Weighted average $= \sum \frac{Wx\%xF}{WxF}$ = 4.85', 9.30% Pb, 7% Zn, 0.77 oz Ag

diluted to W = 5 feet : 5.00', 9.03% Pb, 6.8% Zn, 0.75 oz Ag.

Considering a tonnage factor of 10.5 cu ft/ton, the estimated tonnage with this grade would be 123.8 tons per vertical foot. For a vertical dimension of 100 feet the tonnage would be 12,380 short tons.
Considering 10% mining dilution, grade and tonnage of mined ore material would be 136.18 tons per vertical foot at 8.13% Pb, 6.12% Zn, 0.7 oz Pb.

If we accept a maximum vertical distance of 100 feet, the amount of mined ore material would be 13,618 short tons at 8.13 Pb, 6.12% Zn, 0.7 oz Ag.

Assuming mill recovery figures:

Zn - 80%, Pb - 75%, Ag - 75%

from each ton of ore we would recover:

Pb - 121.95 lb
Zn - 97.92 lb
Ag - 0.52 oz

The average metal prices of the American Metal Market in New York for December, 1973 (from E/MJ, January, 1974, page 46) are, in U.S. currency:

Pb - 17.7¢ per pound
Zn - 27.3¢ per pound
Ag - $3.13 per troy ounce

For our calculations we will, however, consider the more conservative prices of September, 1973 (World Mining, October, 1973):

Pb - 16.5¢ per pound
Zn - 21.0¢ per pound
Ag - $$27070 per troy ounce

which gives a value of recovered metals of $42.08/ton.

2. Trend A

a. Lens No. 5 of the Great South Comet mine

The splitting up of Lens No. 5 at the end of Adit No. 1 and the results obtained by boreholes S.C.11 and S.C.11A, have been discussed already under section titled "Mineralization". It has been advised also that the grade of split 'Alpha' had not been tested by underground sampling because the part immediately south of the junction was stoped over a horizontal length of 40 feet, a vertical range of 40 feet above the adit, and a width of about 12 feet, and because at the end of the stope the roof of the drive had fallen. However, from drilling we know that split 'Alpha', intersected by S.C.11 at about 110 feet south of No. 1 West Crosscut, shows, at about 100 feet below the level of the adit, persistence of pay width and grade: 11.7 feet, 4.47% Pb, 13.3% Zn and 3.58 oz Ag.

In our calculations we will compute for convenience a combined assay and width for split 'Beta' and the section of Lode A3 north of the junction point. Split 'Alpha' will be dealt with separately.

Due to the low grade intersections obtained from S.C.11 and S.C.11A, split 'Alpha' can be extended safely only half of the distance from the horizontal projection of S.C.11. Considering that such low grade values occur in a vertical range of 150 feet, the figure of 80 feet can be taken as the probable maximum vertical dimension of the lens.

Main Lode and Split B

Only the assay results obtained from the channel samples taken in the main drive and in the short west drift (refer to Drawing No. B.164), have been used to calculate the average width and grade of the unmined section of Lens No. 5. The grouping of the sample units within several channels could, however, be sorted in such a way as to yield an average overall width closer to five feet, and, of course, a better average grade.

Data and calculations are tabulated in the adjoining table.

30					225	782.17	2,581.05	542.72

Combined average over a strike length of 70 feet

Width $= \sum \frac{WxF}{F} = 7.5$ feet

Weighted average: $\sum \frac{Wx\%xF}{WxF}$ = 7.5', 3.47% Pb, 11.47% Zn, 2.41 oz Ag.

Considering a tonnage factor of 10.5 cu. ft/ton, and assuming that the lens extends at least 25 feet past the face of the drift for a total strike length of 95 feet, the estimated tonnage would be 71.2 tons per vertical foot which yields, if we assume a vertical dimension of 80 feet : 5,696 short tons at 3.47% Pb, 11.47% Zn and 2.41 oz Ag.

Split 'Alpha'

While the S.C.11 intersection at 1,027' A.S.L. shows pay grade over a width of 11.7 feet, the S.C.12 intersection at 1,201' A.S.L. shows that although the width of the lode has increased, the grade has deteriorated. However, the two values occur in a range of 184 feet, and this wide mineralised structure can probably be extended along the strike half the distance to S.C.10 horizontal projection. For average vertical dimension, taking into account the 40 feet of overhand stoping, a maximum of 80 feet can be considered.

If total length of Split 'Alpha' were 160 feet, the maximum tonnage should be $\frac{160 \times 7.5}{10.5} = 120$ tons per vertical foot, using an average width of 7.5 feet (similar to that of Split 'Beta') as being safer than that of 11.7 feet shown by the S.C.11 intersection.

If the average vertical dimension is 80 feet, the final figure would be 9,600 short tons averaging a grade probably not inferior to that calculated for Split 'Beta'.

Considering that about 1,700 tons were extracted from Stope No. 6, the estimated maximum tonnage of Split 'Alpha' should be of the order of 7,900 short tons.

Altogether, the maximum potential tonnage of Lens No. 5 could be 13,596 short tons averaging 3.47% Pb, 11.47% Zn and 2.41 oz Ag.

If we now assume a 10% mining dilution, tonnage and grade should become:

14,955 short tons at 3.13% Pb, 10.33% Zn and 2.17 oz Ag.

Assuming as valid the same mill recovery figures of Zn = 80%, Pb = 75%, Ag = 75%, from each ton of ore we could recover:

Pb	46.95 lb
Zn	165.28 lb
Ag	1.63 oz

Using, as in the previous case the average metal prices of the American Metal Market for September, 1973, the value of recovered metals would be $46.84 per ton.

b. Borehole Kosminsky Hill No. 1 (1.035' A.S.L. intersection)

K.H.1 intersected ore mineralisation at 1,035' A.S.L. (refer Drg. B160). The intersection averaged, over a width of 6 feet: 6.95% Pb, 6.85% Zn and 2.8 oz Ag.

The horizontal distance over which the ore may persist is limited by the low grade K.H.5 - 1,073' A.S.L. and K.H.13 - 980' A.S.L. intersections.

K.H.1 - 1,035' A.S.L. width and assay can therefore be projected laterally only half-way to the location of the K.H.5 and K.H.13 intersections, delineating a lens of a strike length of about 180 feet. Assuming 80 feet as the maximum possible vertical range, and 10.5 cu. feet/ton as tonnage factor, this lens could yield 8,228 short tons at the above-mentioned grade.

c. Boreholes K.H.6 and K.H.4

The 1,064' A.S.L. and 1,083' A.S.L. intersections of these two boreholes outline a lens which could be about 320 feet long with an average width close to 5.5 feet, but with a grade probably slightly inferior to that of Texins Development's exploration targed (about 11.4% of combined Pb and Zn, and about 2.3 oz of Ag per ton). The estimated length of this lens is, however, above the average in the area and fill-in drilling could indicate that it is actually formed by two isolated pods.

3. Trend E2

Borehole K.H.3 shows a mineralised intersection at 1,238 feet A.S.L. which, over a width of 6.7 feet, averaged 13.84% Pb, 2.37% Zn and 3.02 oz Ag.

This lens has not been satisfactorily tested, the two nearby boreholes K.H.2 and K.H.5 having been depressed to intersect the vein structure far below the common vertical range of the richest pods of the area. We can, however, estimate also for this lens a strike length of 180 feet and a vertical dimension of 80 feet which would yield a tonnage in the order of 9,000 tons at the above reported grade.

4. Trend E1

Borehole K.H.1 intersected at 805' A.S.L. a vein structure which averaged over a width of 7 feet, 13.5% Pb, 1.72% Zn, 13.07 oz Ag. Considering that this vein structure was not intersected by K.H.21 at about 70 feet above the K.H.1 intersection nor by K.H.14 at about 200 feet below, it is possible that this pod might have more limited dimensions than the previous ones. Tentatively, taking a strike length of 100 feet and a vertical dimension of 40 feet, it could yield a tonnage of about 2,600 tons at the above reported grade.

CONCLUSIONS

Summarising, the estimated tonnages of material which, on the basis of Texins Development's exploration target limits, can be considered of "ore grade" are as follows:

Trend W		12,380 short tons
Trend E1 (Lens No. 5		13,596 short tons
Trend E1 (Lens K.H.1		8,228 short tons
Trend E2		9,000 short tons
Trend E1		2,600 short tons
		45,804 short tons

Out of these, only Lens No. 5 has an average grade above 10% Zn.

The total estimated tonnage is far below the minimum limit of 2,000,000 tons set by Texins Development Pty. Ltd. in January, 1973. Further, it seems improbable, knowing the habit of the mineralisation within the tested sections of the Kosminsky-South Comet fracture zone, that such a tonnage could be found in the still untested Climie and Mariposa sections.

Our conclusions are, therefore, that the results obtained to date do not warrant any further work in the prospect area.

Lanfranco Discala
25 March, 1974.

APPENDIX III 1971/8

SUMMARY OF DIAMOND DRILLING IN THE DUNDAS AREA OF WEST TASMANIA E.L.7/68

SEPTEMBER, 1972 - FEBRUARY, 1973

PREPARED FOR

TEXINS DEVELOPMENT PTY. LTD.

BY

GEOPHOTO RESOURCES CONSULTANTS

A.C. JOHNSTON
FEBRUARY, 1973

INTRODUCTION

During the period September, 1972 to February, 1973 a total of 16 diamond drill holes was drilled within the Dundas area of E.L.7/68. Of these, 12 were directed at further investigating the South Comet-Kosminsky fracture zone. The remaining holes were drilled on targets located within the Montezuma North grid. The conclusions drawn from the above programme have been discussed in detail in Geophoto Minerals Reports 1974/4 and 1974/8.

The following, therefore, is a summary of the objective and results of each of the above diamond drill holes.

South Comet 12 (S.C.12)

Objective: S.C.12 was drilled to explore the southern extension of the South Comet-Kosminsky fracture zone.

Results: A wide weakly mineralised section within brecciated siltstones and sandstones of the Hodge formation and associated with abundant siderite veinlets, gave the following results:-

129.9' - 147.9' 0.51% Pb, 0.7% Zn

Minor mineralisation was also intersected in the interval 278.9' - 393.7', and here also associated with siderite veinlets within sporadically brecciated siltstones of the Brewery Junction formation.

South Comet 14 (S.C.14)

Objective: S.C.14 was one of a series of holes designed to test at depth the main South Comet lode zone. In addition, two lode zones which parallel this mineralised trend and about which little was known at the time, would be tested.

Results: Three significantly mineralised sections were intersected in this hole and can be summarised as follows:-

1. 138.5 ft - 146.3 ft 6.45% Pb, 4.36% Zn, 4.69 oz Ag

Within this section PbS and ZnS mineralisation was generally "scattered" throughout. At 139.1 ft "stronger veining" consisted of coarse, zoned, brown sphalerite and sub-ordinate galena within a gangue of siderite. This veining, which occurred within sandstones, siltstones and shales of the Hodge formation, was inclined at 15° to the core axis.

2. 175.9ft - 181.1ft 13.4% Pb, 1.4% Zn, 13 oz. Ag

Mineralisation throughout this section consisted of fine galena and sub-ordinate sphalerite and pyrite, associated with a gangue of siderite. Brecciated sandstone, siltstone and fuchsite conglomerate of the Red Lead formation hosted the above mineralisation.

3. At 518ft (4.5ft true width)
1.10% Pb, 7.14% Zn, 0.13 oz Ag

This mineralisation was encountered at 803ft A.S.L. and represents the main South Comet-Kosminsky lode. Here, the lode material varies from massive, coarse grained, dark brown, sphalerite with sub-ordinate galena and pyrite, to occasional coarse sphalerite associated with siderite veining. Sandstones and siltstones of the Crimson Creek formation host the above mineralisation.

South Comet 15 (S.C.15)

Objective: S.C.15 encountered only one significantly mineralised section. As for S.C.14 above.

Results: S.C.15 encountered only one significantly mineralised section:-

342.9ft - 350ft 6.5% Pb, 0.3% Zn, 2 oz Ag.

In this case, the mineralisation occurs as blebs and veinlets of coarse galena and sphalerite, with pyrite, in "carbonaceous quartzite" and irregular carbonate veinlets. Dark grey slates and quartzites of the oonah formation host the above mentioned mineralisation.

South Comet 16 (S.C.16)

Objective: As for S.C.14 above.

Results: No significant mineralisation was intersected in S.C. 16. Minor mineralisation, however, was encountered at 445.9ft, 485.3ft, 56.7ft and 79.8ft and within a strongly brecciated section, 100ft - 108.3ft. S.C.16 was planned to terminate at 1115.5ft but was abandoned at 576.6ft after penetrating an intensely brecciated zone first encountered at 518.6ft.

South Comet 17 (S.C.17)

Objective: As for S.C.14 above.

Results: S.C.17 intersected the main South Comet lode zone at 607ft A.S.L. where only minor mineralisation was encountered:-

689ft - 690.9ft 1.8% Pb, 0.68% Zn

However, two significantly mineralised sections were intersected and are summarised as follows:-

1. 200.1ft - 205ft 1.5% Pb, 6.2% Zn, 6.2 oz Ag

Within this interval, sphalerite and galena mineralisation is associated with a brecciated zone within sandstones and siltstones of the Hodge formation.

2. 354.3ft - 359.2ft 7.2% Pb, 2.1% Zn, 8.9 oz Ag.

Brecciated siltstones and sandstones from the Razorback formation host the mineralisation in this interval.

South Comet 18 (S.C.18)

Objective: S.C.18 was located near and to the immediate south-east of Adelaide Creek and was directed at the southern extension of the South Comet-Kosminsky fracture zone.

Results: A wide weakly mineralised zone was intersected at 129.9ft, within brecciated siltstones and sandstones of the Hodge formation. The mineralisation, associated with abundant siderite veinlets, gave the following result:-

129.9ft - 148ft	0.51% Pb, 0.7% Zn

Minor mineralisation was also encountered in the interval 278.9ft - 393.7ft and here was associated with siderite veinlets and sporadic brecciation.

South Comet 19 (S.C.19)

Objective: As for S.C.14 above.

Results: Throughout the length of S.C.19, only sporadic weakly mineralised sections were encountered, the best result being 1.95% Pb, 0.64% Zn, in the interval 788.4ft - 771.3ft. The projected South Comet-Kosminsky lode zone was cut at 350ft A.S.L. and here was represented by barren carbonate veining only.

South Comet 21 (S.C.21)

Objective: As for S.C.14 above.

Results: S.C.21 intersected the main South Comet-Kosminsky lode at 520ft A.S.L. where only minor mineralisation was encountered. The weak mineralisation was hosted by brecciated sandstones

and siltstones of the Crimson Creek Formation, and occurred as Pbs and Zns associated with abundant pyritic siderite veinlets. Other weakly mineralised sections were intersected at 413.7ft and 916ft. The latter gave the following results:-

916ft - 920.6ft	1.8% Pb, 3.2% Zn

Kosminsky Hill 19 (K.H. 19)

Objective: K.H.19 was one of a series of holes (K.H.19 to K.H.23) drilled into Kosminsky Hill, to test the lateral extent and mineralisation of the northern portion of the South Comet-Kosminsky fracture zone.

Results: K.H.19 intersected no significant mineralisation. Minor mineralisation in the form of blebs and veinlets of galena, associated with siderite veinlets, was located at 348.8ft - 351.7ft and 377.3ft - 377.6ft. Both of these occurrences were located within dark grey graphitic slates and quartzites of the Oonah Formation.

Kosminsky Hill 20 (K.H.20)

Objective: As for K.H.19 above.

Results: No significant mineralisation was intersected in K.H.20. Minor mineralisation, however, occurred within the interval 147ft - 149.3ft, where veinlets of galena and sphalerite were hosted by massive, cream siderite at the faulted contact between Crimson Creek and Oonah Formations. Brecciation of varying intensity was a common feature throughout the length of this hole, but was particularly intense within the interval 149.4ft - 300ft.

Kosminsky Hill 21 (K.H.21)

Objective: As for K.H.19 above.

Results: K.H.21 intersected two weakly mineralised zones within the intervals 45.9ft - 55.8ft and 85.3ft - 90.2ft. The latter interval gave 0.4% Pb, 2.1% Zn, and was located within a mildly brecciated section of siltstones, mudstones and sandstones belonging to the Crimson Creek formation. Frequent siderite and quartz-siderite veining was associated with the above minor mineralisation.

Kosminsky Hill 23 (K.H.23)

Objective: As for K.H.19 above.

Results: No significant mineralisation was encountered by K.H.23. One weakly mineralised section, however, was located within the interval 411.4ft - 416.3ft and resulted in 0.82% Pb, 1.31% Zn, 0.73 oz Ag. Mineralisation here consisted of scattered 'stringers' of galena and sphalerite (seldom $\geq$ 1/10") associated with abundant siderite veinlets within varicoloured mudstones of the Crimson Creek formation. Minor galena and pyrite mineralisation was also located within the interval 643.9ft - 655.2ft.

Montezuma North 3 (MzN.3) (refer to Drg. No. 1/354)

Objective: MzN.3 was drilled to investigate V.L.F. anomaly No. 1.

Results: No significant mineralisation was intersected by MzN.3. Minor Sn mineralisation, however, was located within the following intervals:-

147.5ft - 152.4ft	0.4% Sn
153.5ft - 158.4ft	0.6% Sn

The Sn mineralisation (cassiterite?) was associated with abundant veinlets of pyrite occurring within disrupted quartzites and black graphitic slates of the Oonah formation. It seems highly likely that the V.L.F. response can be directly related to the pyrite-rich black graphitic slates.

Montezuma North 4 (MzN.4)

Objective: MzN.4 was one of three holes (MzN.4, MzN.5, MzN.6) all drilled from the same location with the following twofold purpose:-

1. To test V.L.F. anomaly No. 2 at depth. This anomaly was supported by mineralisation (mainly pyritic) observed in the old adits (nos. 4, 5 and 6).

2. To test at depth a jamesonite-pyrite vein. This vein, which assayed up to 24% Sb, 33% Pb and 34oz Ag, corresponds fairly well to V.L.F. anomaly No. 2 and was uncovered while preparing the access road to the above sites.

Results: Only very minor Pb and Sb mineralisation was encountered by MzN.4 which was drilled on a bearing of 265°, almost perpendicular to the above-mentioned vein. The surface mineralisation, however, was intersected at 410ft (1,748ft A.S.L.) and took the form of a strong development of pyrite mineralisation, within disrupted quartzites and black slates of the Oonah formation. A 6.6ft section of this mineralisation gave the following encouraging assay, particularly for Sn and Ag:-

410.1ft - 416.7ft 0.7% Sn, 3.8 oz Ag

Montezuma North 5 (MzN.5)

Objective: As for MzN.4 above.

Result: MzN.5 was drilled on a bearing of 300°T and intersected the vein mineralisation at 230ft and 1,929ft A.S.L., where it had an apparent width of about five feet. The mineralisation was dominated by massive pyrite carrying minor galena and jamesonite, within disrupted black slates and quartzites of the Oonah formation. Systematic sampling of this and other pyrite-rich sections resulted in only very minor associated Sn mineralisation and insignificant Ag values. The highest Sn value was 0.2% Sn for the interval 220.3ft - 223ft.

Montezuma North 6 (MzN.6)

Objective: As for MzN.4 above.

Result: MzN.6 was drilled in a bearing of 220°T with similarly poor results to MzN.5. The only evidence of the jamesonite-pyrite vein was a 10" section of massive pyrite at 164ft and 1,831ft A.S.L., again within disrupted quartzites and black slates of the Oonah formation. Minor veinlets of

galena and sphalerite were encountered at 57ft, 217ft, 233ft and 386ft, and thin pyrite veinlets were abundant throughout the length of the hole. Several pyrite-rich sections were sampled for Sn content with disappointing results. The highest assay was 0.24% Sn in the interval 381.3ft - 382.8ft.

Frank,

Note different results obtained for Sn by Geochem & Assay techniques. From these results and our experience it would appear the cut-off point is approximately 0.05% Sn, i.e. Geochem determinations with samples from EL.7/68 whose results are >0.05% must be considered suspect, i.e. will read low. The assay method will give the correct result.

Ray

METHODS: Cu, Pb, Zn, Ag by G.R.C. NO. 101
Bi by G.R.C. NO. 102
Sb by G.R.C. NO. 108
Sn by G.R.C. NO. 5 & G.R.C. NO. 105
BLD = Below limit of detection

								MINERALIZATION: Visible mineralization confined to three intervals. (1) 217.9-218.1m
								(2) 220.3-222.6m, (3) 226.8-227.8,. Interval (1) carries significant galens/sphalerite
								mineralization as patches and veinlets (to 6 cm true width) associated with pyrite
								and patchy siderite veining roughly inclined at 38° c/a; (2) and (3) (1) but dominately
								pyrite associated with random siderite veinlets very minor Pb, Zn.
228.3m	251.5m			€c				SILTSTONE: Black, highly graphitic 228.3m-
								236.6m highly sheared/brecciated and injected by numerous randomly tated amber
								carbonate stringers/veinlets. MINERALIZATION:
								pyrite abundant throughout and commonly
								associated with carbonate veining. Significant galena mineralization over the
								following intervals, (1) 233.1m-233.8m-
								dominately as fine network of fine veinlets
								permeated throughout a pyrite-rich carbonate gangue. (2) 237.8m-238m-galena as
								irregular veinlets (to 5mm true width) in
								brecciated section and associated with
								random pyrite-rich carbonate veinlets.
								Remainder; dominately siltstone, highly

								superjacent sandstone exhibits depositional breccia of dark grey siltstone.
200.4	203.4m							BRECCIA: highly sheared/brecciated and dolomitized section including pale grey quartzose dolomitic sandstone and highly sheared graphitic siltstone fragments; commonly pyritic and permeated with numerous randomly orientated carbonate veinlets; soft pale green talcose material commonly lines joint and fracture surfaces.
203.4	215.5m							VOLCANIC: dark grey/black highly sheared, carbonized and dolomitized volcanic; commonly pyritic and permeated with numerous randomly orientated very fine veinlets and stringers carbonate; mottled appearance due to pink now kaolinized feldspars.

LEGEND

CAMBRIAN

Hodge Formation (DUNDAS GROUP)

- Ch1 — SILTSTONE grey to greenish, micaceous, some limonite staining and occasionally arenaceous. Lesser amounts of grey shale and carbonate veins.
- Ch2 — SHALE black to dark grey to light brown, with interbedded arenaceous layers and carbonaceous seams.
- Ch3 — SILTSTONE grey to greenish, siliceous interbedded with khaki and dark grey shale. Minor amounts of light grey, quartzose sandstone.
- Ch4 — CONGLOMERATE subrounded, black shale fragments in a silty matrix.
- Ch5 — SHALE grey to black, brecciated with fuchsite occurring along joint planes.

Serpentine — Cs — DOLOMITIZED VOLCANICS ? grey, fine grained mosaic of dolomite and partially dolomitized unidentified anhedral crystals. In part brecciated with considerable quartz carbonate veining.

Crimson Ck. Formation — Cc — SHALE black, khaki, in graphitic with carbonate veining interbedded with light grey, occasionally arenaceous siltstone.

PROTEROZOIC

Oonah Formation — Puo — SLATE black micaceous with well developed slatey cleavage.

CAMBRIAN

DUNDAS GROUP

Hodge Formation

- €h1 — SILTSTONE: dark grey, finely laminated and banded with pale grey micaceous, dolomitic sandstone.
- €h2 — SILTSTONE: medium-dark grey, laminated and interbedded with pale grey sandstone — both distinctly micaceous.
- €h3 — SANDSTONE: medium-dark grey, micaceous and dolomitic, interbedded with thin bands dark grey siltstone often giving coarsely laminated appearance.
- €h4 — GRIT: dark grey.

Red Lead Formation

- €r — CONGLOMERATE: grey-sub-rounded pebbles of pale-dark grey quartzite and medium-dark grey siltstone, set in dolomitic gritty/sandy matrix — irregular patches dark green fuchsite.

Crimson Creek Formation

- €c1 — SILTSTONE/FINE SANDSTONE: medium grey, dolomitic and often quartzose.
- €c2 — DOLOMITIC: pale grey, arenaceous.
- €c3 — SILTSTONE: dark grey-black, pyrite and highly graphitic.
- €c4 — META-VOLCANICS: dark grey-green grey, carrying abundant white/pink kaolinized feldspar.
- €c5 — SLATE: black, pyrite and highly graphitic.
- €c6 — SANDSTONE: pale grey, dolomitic and commonly pyritic, interbedded with thin bands khaki/dark grey siltstones and mudstones.
- €c7 — MUDSTONES AND SILTSTONES: khaki, pale-dark grey, dolomitic, soft sediment deformation structures common; some thinly interbedded sandstone.

LEGEND

CAMBRIAN
- Crimson Ck. Formation
  - Cc_1 — SHALE AND SILTSTONE: light to dark grey, arenaceous, partly laminated.
  - Cc_2 — SANDSTONE AND SILTSTONE: light grey to dark grey and black.
  - Cc_3 — SLATE AND SHALE: dark grey to black graphitic.
  - Cc_4 — MUDSTONE: tan and pink
- Serpentine
  - $Cs?$ — SERPENTINIZED (?) ROCK: grey, called calc-silicate in log, possibly intrusive

UPPER PROTEROZOIC
- Oonah Formation
  - Puo — SLATE AND QUARTZITE: black and dark grey, quartzite is micaceous.

Fault, dashed where indefinite, questioned where inferred, arrows showing relative movement.

Contact, dashed where indefinite, questioned where inferred.
